

This website is an online medium through which I've presented myself and my work. It's primary audience is prospective employers and professional connections who are interested in evaluating my work and expertise to evaluate my candidacy for a particular employment position. The secondary audience would be friends and/or family who are interested in the work that I've done and may also be a part of my professional network. I've categorized my experience into 4 separate subjects, hoping that an employer in a specific field will easily be able to find information that is relevant to a certain prospective job. However, the home page treats all four categories with the same importance, and portrays that I am all of these titles: a creative, a techie, a performer, and a student. (Student, being also my miscellaneous category). I've titled the categories as descriptive nouns, meaning I can say "I am" a creative or a techie. I've chosen this content because I want the audience to see how I define myself. Across the pages for each category, I've given titles to the work/experience I've done, followed by a short description. I styled the margins and paddings of most elements for better readability, and I've also implemented a media.css stylesheet for responsive design.

The PHP elements of this webpage include PHP includes for the bottom contact div and the navigation bar. The bottom contact div acts much like a footer, and simply prints HTML. I've decided to use the PHP include however so that it is easier to change this reoccurring feature if I'd like to in the future. The navigation has an include for a similar reason, and features an associative array and a foreach loop that iterates through the nav menu items and links. On the contact page, there is a form which takes in user input including a first and last name, email, subject, and message so that the user can send me an email via the webpage. The form features text, email, and a message input, and upon the submit button, sends the user to a different screen. The PHP then sends me an email and sends a confirmation email to the user that the message has been sent.
